The many faces of Exponential Weights in Online Learning

Dirk van der Hoeven, Tim van Erven, and Wojciech Kotłowski

06-2018

Motivation: Football prediction

- Every football match t there are K models that predict the outcome of the match.
- Form probability distribution p_t(k) and play the weighted average of the K predictions: E_{pt(k)}[w_k].
- ► After match: observe losses f_t(w_k) and suffer loss f_t(𝔅_{pt}(k)[w_k]).
- Improve probability distribution p_t(k) → p_{t+1}(k) based on observed losses.

Exponential Weights

Input: a convex set of distributions \mathcal{P} over w, a prior $P_1 \in \mathcal{P}$ and learning rates $\eta_1 \geq \eta_2 \geq \cdots \geq \eta_T > 0$

Lazy:

- $\begin{array}{l} 1 \text{ update step:} \\ \tilde{P}_{t+1} = \arg\min_{P} \ \mathbb{E}_{P}\left[\sum_{s=1}^{t} f_{s}(w)\right] + \frac{1}{\eta_{t}} \operatorname{\mathsf{KL}}(P \| P_{1}) \end{array}$
- 2 projection step: $P_{t+1} = \arg \min_{P \in \mathcal{P}} \operatorname{KL}(P \| \tilde{P}_{t+1})$

Greedy:

- $\begin{array}{l} 1 \hspace{0.1 cm} \text{update step:} \\ \tilde{P}_{t+1} = {\sf arg\,min}_{P} \hspace{0.1 cm} \mathbb{E}_{P}[f_{t}(w)] + \frac{1}{\eta_{t}} \, \mathsf{KL}(P \| P_{t}) \end{array}$
- 2 projection step: $P_{t+1} = \arg \min_{P \in \mathcal{P}} \operatorname{KL}(P \| \tilde{P}_{t+1})$

The algorithm gets its name from the distributions \tilde{P}_t , whose densities have the following exponential forms:

$$d\tilde{P}_{t+1}(w) = \frac{e^{-\eta_t \sum_{s=1}^t f_s(w)} dP_1(w)}{\int e^{-\eta_t \sum_{s=1}^t f_s(w)} dP_1(w)} \qquad \text{(lazy EW)}$$
$$d\tilde{P}_{t+1}(w) = \frac{e^{-\eta_t f_t(w)} dP_t(w)}{\int e^{-\eta_t f_t(w)} dP_t(w)} \qquad \text{(greedy EW)}.$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Regret Exponential Weights

Let $Q \in \mathcal{P}$ be any comparator distribution such that $\mathsf{KL}(Q \| \tilde{P}_t) < \infty$ for all t, let $\{w_t \in \mathcal{W}\}_{t=1}^T$ be the actions of any learner, and define $\eta_0 \stackrel{\text{def}}{=} \eta_1$. Then lazy EW satisfies

$$\mathbb{E}_{u \sim Q}[\mathcal{R}(u)] \leq \frac{1}{\eta_{\mathcal{T}}} \mathsf{KL}(Q \| P_1) + \sum_{t=1}^{\mathcal{T}} \Big\{ \underbrace{f_t(w_t) + \frac{1}{\eta_{t-1}} \ln \mathbb{E}_{P_t(w)}\left[e^{-\eta_{t-1}f_t(w)}\right]}_{\text{``mixability gap''}} \Big\}.$$

Greedy EW satisfies:

$$\mathbb{E}_{u \sim Q}[\mathcal{R}(u)] \leq \frac{1}{\eta_1} \operatorname{KL}(Q \| P_1) + \left(\frac{1}{\eta_T} - \frac{1}{\eta_1}\right) \max_{t=2,\dots,T} \operatorname{KL}(Q \| P_t) \\ + \sum_{t=1}^T \left\{ \underbrace{f_t(w_t) + \frac{1}{\eta_t} \ln \mathbb{E}_{P_t(w)}\left[e^{-\eta_t f_t(w)}\right]}_{\text{``mixability gap''}} \right\}.$$

Regret Exponential Weights

Proof structure in most settings

- Bound the mixability gap
- ► Find Q for which the expected loss under Q together with KL(Q||P1) can be related to the loss of a deterministic comparator.

Unless specified otherwise

- $\blacktriangleright w_t = \mathbb{E}_{P_t}[w]$
- $\blacktriangleright \mathcal{P} = \{ P : \mathbb{E}_P[w] \in \mathcal{W} \}$

A standard approach in OCO is to lower-bound the convex losses f_t by their tangent at w_t :

$$\sum_{t=1}^{T} \left(f_t(oldsymbol{w}_t) - f_t(oldsymbol{u})
ight) \leq \sum_{t=1}^{T} ig(\langle oldsymbol{w}_t, oldsymbol{g}_t
angle - \langle oldsymbol{u}, oldsymbol{g}_t
angle ig),$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

where $oldsymbol{g}_t =
abla f_t(oldsymbol{w}_t)$

Standard approach: Mirror Descent

- B_{F*}(u||w) = F^{*}(u) − F^{*}(w) − ∇F^{*}(w)^T(u − w) denotes the Bregman divergence generated by F^{*}.
- F^{*}(w) = sup_θ⟨w, θ⟩ − F(θ) denotes the convex conjugate of F.

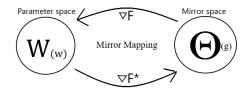

Lazy Mirror Descent:

$$egin{aligned} & ilde{w}_{t+1} = rgmin_{oldsymbol{w}} \sum_{s=1}^t \langle oldsymbol{w}, oldsymbol{g}_s
angle + rac{1}{\eta_t} B_{F^*}(oldsymbol{w} \| oldsymbol{w}_1) \ &oldsymbol{w}_{t+1} = rgmin_{oldsymbol{w}\in\mathcal{W}} B_{F^*}(oldsymbol{w} \| oldsymbol{ ilde{w}}_{t+1}). \end{aligned}$$

Greedy Mirror Descent:

$$egin{aligned} & ilde{w}_{t+1} = rgmin_w \langle w, oldsymbol{g}_t
angle + rac{1}{\eta_t} B_{F^*}(w \| oldsymbol{w}_t) \ & w_{t+1} = rgmin_{oldsymbol{w}\in\mathcal{W}} B_{F^*}(w \| oldsymbol{ ilde{w}}_{t+1}). \end{aligned}$$

Interpretation Mirror Descent

Common choices for *F*:

- Gradient Descent: $F(\theta) = \frac{1}{2} \|\theta\|_2^2$
- Unnormalized Relative entropy: $F(\theta) = \sum_{i=1}^{d} e^{\theta_i}$
- Exponentiated Gradient (±): $F(\theta) = \log(\sum_{i=1}^{d} e^{\theta_i})$

Mirror Descent as Exponential Weights

We consider prior from exponential families:

- $\blacktriangleright \text{ Have form } \mathcal{E} = \{ P_{\boldsymbol{\theta}} \mid \mathrm{d} P_{\boldsymbol{\theta}}(w) = e^{\langle \boldsymbol{\theta}, w \rangle F(\boldsymbol{\theta})} \mathrm{d} \mathcal{K}(w), \boldsymbol{\theta} \in \Theta \}$
- Nonnegative carrier measure K
- Cumulant generating function $F(\theta) = \ln \int e^{\langle \theta, w
 angle} \mathrm{d} K(w)$

- Parameter space $\Theta = \{ oldsymbol{ heta} \mid F(oldsymbol{ heta}) < \infty \} \subset \mathbb{R}^d$
- Called *regular* if Θ is an open set

Mirror Descent as Exponential Weights

Theorem

Suppose F is the cumulant generating function of a regular exponential family \mathcal{E} . Then the lazy and greedy versions of MD predict with the means $w_t = \mathbb{E}_{P_t}[w]$ of lazy and greedy EW on the linearized losses with the same η_t , prior P_{θ_1} for $\theta_1 = \nabla F^*(w_1)$ and $\mathcal{P} = \{P : \mathbb{E}_P[w] \in \mathcal{W}\}.$

Lazy EW:

$$\mathop{\mathbb{E}}_{P_{t+1}}[w] = w_{t+1} = rgmin_{w\in\mathcal{W}}\sum_{s=1}^t \langle w, g_s
angle + rac{1}{\eta_t} B_{\mathcal{F}^*}(w\|w_1)$$

Greedy EW:

$$\mathop{\mathbb{E}}_{P_{t+1}}[w] = w_{t+1} = \mathop{\mathrm{arg\,min}}_{w\in\mathcal{W}} \langle w, g_t
angle + rac{1}{\eta_t} B_{\mathcal{F}^*}(w\|w_t)$$

Greedy MD as Greedy EW proof

We can restrict P to an exponential family:

$$\begin{split} & \min_{P \in \mathcal{P}} \left\{ \mathbb{E}_{P}[\langle \boldsymbol{w}, \boldsymbol{g}_{t} \rangle] + \frac{1}{\eta_{t}} \operatorname{KL}(P \| P_{t}) \right\} \\ &= \min_{\boldsymbol{\mu} \in \mathcal{W}} \min_{P : \mathbb{E}_{P}[\boldsymbol{w}] = \boldsymbol{\mu}} \left\{ \mathbb{E}_{P}[\langle \boldsymbol{w}, \boldsymbol{g}_{t} \rangle] + \frac{1}{\eta_{t}} \operatorname{KL}(P \| P_{t}) \right\} \\ &= \min_{\boldsymbol{\mu} \in \mathcal{W}} \min_{P \in \mathcal{E} : \mathbb{E}_{P}[\boldsymbol{w}] = \boldsymbol{\mu}} \left\{ \langle \boldsymbol{\mu}, \boldsymbol{g}_{t} \rangle + \frac{1}{\eta_{t}} \operatorname{KL}(P \| P_{t}) \right\}, \end{split}$$

where the last equality is due to Theorem 3.1.4 in Ihara (1993).

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Greedy MD as Greedy EW proof

To finish the proof we use a result from Banerjee et al. (2005); Nielsen and Nock (2010). Let $\mu_P = \mathbb{E}_P[w]$. For $Q, P \in \mathcal{E}$:

$$\mathsf{KL}(P\|Q) = B_F(\theta_Q\|\theta_P) = B_{F^*}(\mu_P\|\mu_Q).$$

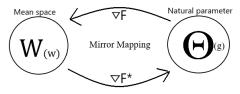

We now have:

$$egin{aligned} & P_{t+1} = rgmin_{P\in\mathcal{E}:oldsymbol{\mu}_P\in\mathcal{W}} \left\{ \langle oldsymbol{\mu}_P, oldsymbol{g}_t
angle + rac{1}{\eta_t} \, \mathsf{KL}(P \| P_t)
ight\} \ & = rgmin_{P\in\mathcal{E}:oldsymbol{\mu}_P\in\mathcal{W}} \left\{ \langle oldsymbol{\mu}_P, oldsymbol{g}_t
angle + rac{1}{\eta_t} B_{F^*}(oldsymbol{\mu}_P \| oldsymbol{\mu}_{P_t})
ight\}, \end{aligned}$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

which coincides with the definition of greedy Mirror Descent.

MD as EW interpretation

Before we had:

- Gradient Descent: $F(\theta) = \frac{1}{2} \|\theta\|_2^2$
- Unnormalized Relative entropy: $F(\theta) = \sum_{i=1}^{d} e^{\theta_i}$
- Exponentiated Gradient (±): $F(\theta) = \log(\sum_{i=1}^{d} e^{\theta_i})$

Now we have:

- Gradient Descent: Gaussian Prior
- Unnormalized Relative entropy: Poisson Prior
- ► Exponentiated Gradient (±): Multinomial Prior (1 trial)

Quadratic losses

We assume that the losses f_t satisfy quadratic lower bounds:

$$f_t(\boldsymbol{w}) - f_t(\boldsymbol{w}_t) \geq \langle \boldsymbol{w} - \boldsymbol{w}_t, \boldsymbol{g}_t
angle + rac{1}{2} (\boldsymbol{w} - \boldsymbol{w}_t)^\intercal \boldsymbol{M}_t(\boldsymbol{w} - \boldsymbol{w}_t) =: \ell_t(\boldsymbol{w}),$$

where M_t is a positive semi-definite matrix.

We treat two cases:

- α -strongly convex loss functions: $M_t = \alpha I$
- α -exp concave loss functions: $M_t = \beta g_t g_t^T$, where $\beta = \frac{1}{2} \min\{\frac{1}{4GB}, \alpha\}$, assuming $\|g_t\|_2 \leq G$ and $B = \max_{w, u \in W} \|w u\|_2$

Quadratic losses: Gaussian prior

Theorem

Let $P_1 = \mathcal{N}(w_1, \Sigma_1)$. Both versions of the Exponential Weights algorithm, run on ℓ_t with learning rate η and $\mathcal{P} = \{P : \mathbb{E}_P[w] \in \mathcal{W}\}$, yield a multivariate normal distribution $P_{t+1} = \mathcal{N}(w_{t+1}, \Sigma_{t+1})$. Furthermore for all $u \in \mathbb{R}^d$ both versions of EW satisfy:

$$\mathcal{R}_{\mathcal{T}}(\boldsymbol{u}) \leq rac{1}{2\eta} (\boldsymbol{w}_1 - \boldsymbol{u})^{\intercal} \boldsymbol{\Sigma}_1^{-1} (\boldsymbol{w}_1 - \boldsymbol{u}) + rac{\eta}{2} \sum_{t=1}^{\mathcal{T}} \boldsymbol{g}_t^{\intercal} \boldsymbol{\Sigma}_{t+1} \boldsymbol{g}_t.$$
 (2)

Quadratic losses: Gaussian prior

Lazy EW Gaussian prior:

$$egin{aligned} & \Sigma_{t+1}^{-1} = \Sigma_t^{-1} + \eta M_t \ & ilde{w}_{t+1} = ilde{w}_t - \eta \Sigma_{t+1} g_t \ & w_{t+1} = rgmin_{w\in\mathcal{W}} (w - ilde{w}_{t+1})^\intercal \Sigma_{t+1}^{-1} (w - ilde{w}_{t+1}) \end{aligned}$$

Greedy EW Gaussian prior:

$$egin{aligned} & \Sigma_{t+1}^{-1} = \Sigma_t^{-1} + \eta M_t \ & ilde{w}_{t+1} = w_t - \eta \Sigma_{t+1} g_t \ & w_{t+1} = rgmin_{w \in \mathcal{W}} (w - ilde{w}_{t+1})^\intercal \Sigma_{t+1}^{-1} (w - ilde{w}_{t+1}) \end{aligned}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Strongly convex loss functions

- For α-strongly convex loss functions the standard approach is to use Greedy Gradient Descent with learning rates η_t = 1/(αt) (Hazan et al., 2007)
- Greedy EW on $\ell_t(w)$ with *fixed* learning rate η and Gaussian prior $P_1 = \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I})$ yields greedy GD with $\eta_t = 1/(\frac{1}{\eta\sigma^2} + \alpha t)$

► Regret EW:
$$\mathcal{R}_{\mathcal{T}}(\boldsymbol{u}) \leq \frac{G^2}{2\alpha} \ln \left(\frac{\frac{1}{\eta \sigma^2 + \alpha T}}{\frac{1}{\eta \sigma^2 + \alpha}} \right) + \frac{G^2}{\frac{2}{\eta \sigma^2 + 2\alpha}} + \frac{D^2}{2\eta \sigma^2}$$

► The standard learning rate and corresponding regret bound for GD (Hazan et al., 2007) correspond to the limiting case $\eta\sigma^2 \rightarrow \infty$

Exp-concave loss functions

- For α-exp-concave loss functions the standard approach is to use the Online Newton Step algorithm (Hazan et al., 2007)
- Exponential Weights on $\ell_t(w)$ with Gaussian prior $\mathcal{N}(\mathbf{0}, \sigma^2 I)$ leads to the Online Newton Step algorithm

► Regret EW:
$$\mathcal{R}_{\mathcal{T}}(\boldsymbol{u}) \leq \frac{d}{2\beta} \ln \left(1 + \frac{\eta \sigma^2 \beta G^2 \mathcal{T}}{d}\right) + \frac{D^2}{2\eta \sigma^2}$$

• To obtain the standard regret bound set $\eta\sigma^2 = \beta D^2$

Adaptive Expert Algorithms

Online Linear Optimization with Bandit Feedback

Expert setting

- ▶ Linear losses $f_t(w) = \langle w, g_t \rangle$ over the simplex $W = \{w : w_i \ge 0, \sum_{i=1}^d w_i = 1\}$, with $g_{t,i} \in [0, 1]$
- Instantaneous regret in round t with respect to expert i is $r_t(i) = f_t(w_t) f_t(e_i)$

• Total Regret $\mathcal{R}_T(i) = \sum_{t=1}^T r_t(i)$

Adaptive algorithms

- Standard algorithms requires the learner to specify η
- \blacktriangleright η usually specified to guard against worst case, algorithm may be slow to converge
- \blacktriangleright To specify η one may require knowledge of unknown quantities

Solution: learn the optimal η .

Adaptive algorithms regret

Define
$$\mathcal{V}_T(i) = \sum_{t=1}^T r_t(i)^2$$
.

► Iprod, Squint:

$$\mathbb{E}_{\hat{\pi}}\left[\mathcal{R}_{\mathcal{T}}(i)\right] = O\left(\sqrt{\mathbb{E}_{\hat{\pi}}[\mathcal{V}_{\mathcal{T}}(i)]\Big(\operatorname{\mathsf{KL}}(\hat{\pi}\|\pi) + \ln\ln\mathcal{T}\Big)}\right)$$

Coin Betting:

$$\mathop{\mathbb{E}}_{\hat{\pi}}\left[\mathcal{R}_{T}(i)\right] \leq \sqrt{3T\left(\mathsf{KL}(\hat{\pi}\|\pi) + 3\right)}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Surrogate Task

- Surrogate loss: $\ell_t(\eta, i) = -\ln(1 + \eta r_t(i))$
- ▶ Predictions take the form of joint distributions P_t on (η, i) for $\eta \in [0, 1]$
- Map back to predictions in the original task via $w_t = rac{\mathbb{E}_{P_t}[\eta e_i]}{\mathbb{E}_{P_t}[\eta]}$
- Aim: achieve small *mix-regret* with respect to any comparator distribution Q on (η, i)

Mix regret

Mix regret:

$$S(Q) = \sum_{t=1}^{T} - \ln \mathbb{E}_{P_t} \left[e^{-\ell_t(\eta, i)} \right] - \mathbb{E}_Q \left[\sum_{t=1}^{T} \ell_t(\eta, i) \right].$$

If the learner can guarantee

$$0 \leq \sum_{t=1}^{T} \mathbb{E}[\ell_t(\eta, i)] + S(Q)$$

then use $-\ln(1+x) \leq -x + x^2$ for $|x| \leq \frac{1}{2}$ to obtain:

$$0 \leq \sum_{t=1}^{T} \underset{Q}{\mathbb{E}}[-\eta r_t(i) + \eta^2 r_t(i)^2] + S(Q)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

EW is the solution

How to guarantee $0 \leq \sum_{t=1}^{T} \mathbb{E}_{Q}[\ell_{t}(\eta, i)] + S(Q)$?

Use Exponential weights on ℓ_t with predictions $w_t = \frac{\mathbb{E}_{P_t}[\eta e_i]}{\mathbb{E}_{P_t}[\eta]}$:

$$\sum_{t=1}^{T} \mathbb{E}_{Q}[\ell_{t}(\eta, i)] + S(Q) = \prod_{t=1}^{T} \mathbb{E}_{P_{t}}\left[e^{-\ell_{t}(\eta, i)}\right]$$
$$= \prod_{t=1}^{T-1} \mathbb{E}_{P_{t}}\left[e^{-\ell_{t}(\eta, i)}\right] \mathbb{E}_{P_{T}}\left[1 + \eta r_{T}(i)\right] = 0$$

EW is the solution

- Since the surrogate loss is 1-exp-concave there is no mixability gap to pay
- ► Running EW with constant learning rate 1 on ℓ_t achieves S(Q) ≤ KL(Q||P₁) for any Q

This gives

$$\sum_{t=1}^{T} \mathbb{E}_{Q}[\eta r_{t}(i)] \leq \sum_{t=1}^{T} \mathbb{E}_{Q}[\eta^{2} r_{t}(i)^{2}] + \mathsf{KL}(Q||P1)$$

Regret Iprod

Theorem

If we use EW in the surrogate OCO task with learning rate 1 and any product prior $P_1 = \gamma \times \pi$ for γ a distribution on $\eta \in [0, \frac{1}{2}]$ and π a distribution on *i*, and we take as comparator $Q = \gamma(\eta \mid \eta \in [\hat{\eta}/2, \hat{\eta}]) \times \hat{\pi}$ for any $\hat{\eta} \in [0, \frac{1}{2}]$ and distribution $\hat{\pi}$ on *i* that can both depend on all the losses, then

$$\mathbb{E}_{\hat{\pi}}\left[\mathcal{R}_{\mathcal{T}}(i)\right] \leq 2\hat{\eta} \mathbb{E}_{\hat{\pi}}[\mathcal{V}_{\mathcal{T}}(i)] + \frac{2}{\hat{\eta}} \Big(\operatorname{KL}(\hat{\pi} \| \pi) - \ln \gamma([\hat{\eta}/2, \hat{\eta}]) \Big).$$
(3)

After optimizing $\hat{\eta}$, this leads to an adaptive regret bound of

$$\mathbb{E}_{\hat{\pi}}\left[\mathcal{R}_{\mathcal{T}}(i)\right] = O\left(\sqrt{\mathbb{E}_{\hat{\pi}}[\mathcal{V}_{\mathcal{T}}(i)]\Big(\operatorname{\mathsf{KL}}(\hat{\pi}\|\pi) + \ln \ln \mathcal{T}\Big)}\right) \quad \text{for all } \hat{\pi}$$

Squint

- EW with a continuous prior on η for the iProd surrogate losses requires evaluating a *t*-degree polynomial in η in every round: O(T²) total running time
- By choosing the slightly larger surrogate loss ℓ_t(η, i) = −ηr_t(i) + η²r_t(i)² we turn Iprod into Squint: O(T) total running time
- Exactly the same regret guarantees as iProd:

$$\mathbb{E}_{\hat{\pi}}\left[\mathcal{R}_{\mathcal{T}}(i)\right] = O\left(\sqrt{\mathbb{E}_{\hat{\pi}}[\mathcal{V}_{\mathcal{T}}(i)]\Big(\operatorname{\mathsf{KL}}(\hat{\pi}\|\pi) + \ln\ln\mathcal{T}\Big)}\right) \qquad \text{for all } \hat{\pi}$$

Coin betting

We study a variant of the Coin Betting algorithm for experts of Orabona and Pál (2016)

- ▶ Idea: Split the learning of $\eta \in [0, 1]$ and *i* into separate steps
- restrict $P_t(\eta \mid i)$ to be a point mass on some η_t^i
- Choose ηⁱ_t to achieve small regret for the surrogate loss

$$\ell_t^i(\eta) = -\frac{1 + r_t(i)}{2} \ln \frac{1 + \eta}{2} - \frac{1 - r_t(i)}{2} \ln \frac{1 - \eta}{2} - \ln 2$$

• Learn *i* for the surrogate losses $\tilde{\ell}_t(i) = -\ln(1 + \eta_t^i r_t(i))$

Mix-regret Coin Betting

For $\eta \in [0,1]$ and $\hat{\pi}$ a distribution on *i*, let

$$S_{T}^{i}(\eta) = \sum_{t=1}^{T} \ell_{t}^{i}(\eta_{t}^{i}) - \sum_{t=1}^{T} \ell_{t}^{i}(\eta) \quad (\text{regret log loss})$$
$$\tilde{S}_{T}(\hat{\pi}) = \sum_{t=1}^{T} - \ln \sum_{i \sim P_{t}}^{\mathbb{E}} \left[e^{-\tilde{\ell}_{t}(i)} \right] - \mathbb{E} \left[\sum_{t=1}^{T} \tilde{\ell}_{t}(i) \right]$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

be the mix-regret in the two surrogate OCO tasks.

Regret Coin Betting

Theorem

If we use EW with learning rate 1 and prior π on i for the losses $\tilde{\ell}_t$, and for the losses ℓ_t^i we let η_t^i be the mean of lazy EW with learning rate 1 and with prior on $\eta \in [-1, +1]$ such that $\frac{1+\eta}{2}$ has a beta-distribution $\beta(a, a)$ with $a = \frac{T}{4} + \frac{1}{2}$ and with projections onto $\mathcal{P} = \{P \mid \mathbb{E}_P[\eta] \in [0, 1]\}$, then

$$\mathbb{E}_{\hat{\pi}}\left[\mathcal{R}_{\mathcal{T}}(i)\right] \leq \sqrt{3\mathcal{T}\left(\mathsf{KL}(\hat{\pi}\|\pi) + 3\right)} \qquad \text{for any } \hat{\pi} \text{ on } i.$$

Resulting algorithm

- \blacktriangleright Lazily projecting onto $\eta \in [0,1]$ simply amounts to clipping at 0

• Combining the above we get $\eta_t^i = \max\left\{\frac{\mathcal{R}_{t-1}(i)}{t-1+2a}, 0\right\}$

• Predict with
$$m{w}_t = rac{\mathbb{E}_{\mathcal{P}_t(i)}[\eta_t^i e_i]}{\mathbb{E}_{\mathcal{P}_t(i)}[\eta_t^i]}$$

Interpretation Regret Coin Betting

We can now explain three design choices by Orabona and Pál (2016):

- ▶ δ-shifted KT-Potential function: naturally arises in our proof when we bound the regret Sⁱ_T(R⁺_T(i)/T) for EW
- ► The choice for δ , which is simply specifying a prior with most mass in a region of order $1/\sqrt{T}$ around $\eta = 0$
- ► The clipping of the unnormalized weights $\tilde{p}_t(i)\eta_t^i$ to 0 when $\mathcal{R}_{t-1}(i) < 0$, which in our presentation happens automatically

Organization

Introduction

Exponential Weights

Convex Losses

Quadratic losses

Strongly convex loss functions Exp-concave loss functions

Adaptive Expert Algorithms

Online Linear Optimization with Bandit Feedback

Online Linear Optimization with Bandit Feedback

- ▶ Linear losses $f_t(w) = \langle w, g_t \rangle \in [-1, +1]$
- Instead of seeing the vectors g_t we only observe the loss $f_t(w_t)$ for the algorithm's choice w_t
- The algorithm is allowed to randomize its choice w_t
- ▶ Goal: minimize the expected regret E[R_T(u)], where the expectation is with respect to the algorithm's randomness

Standard solution SCRiBLe (Abernethy et al., 2012):

Mirror Descent with self concordant barrier function F*

Sample based on the spectrum of the Hessian of F*

Sampling from EW distribution

We consider the EW algorithm with fixed learning rate η and uniform prior distribution P_1 over W. Let R be a fixed "exploration" distribution chosen to be John's exploration.

1 for
$$t = 1, 2, ..., T$$
 do

2 Sample $oldsymbol{w}_t \sim oldsymbol{Q}_t$, where $oldsymbol{Q}_t = (1-\gamma) oldsymbol{P}_t + \gamma oldsymbol{R}$

3 Observe
$$f_t(w_t) = \langle w_t, g_t
angle$$

- 4 Constructs a random unbiased estimate \tilde{g}_t
- 5 Update P_t to P_{t+1} based on $\tilde{f}_t(w_t) = \langle w_t, \tilde{g}_t \rangle$

Linear Bandits with EW

When η and γ are appropriately chosen, this algorithm achieves expected regret of order $O(d\sqrt{T \ln T})$, which is the best known expected regret.

Compared to SCRiBLe:

- Instead of sampling from the spectrum of the Hessian we sample from the EW distribution
- We achieve a regret bound that is a factor $O(\sqrt{d})$ better
- A proof outline of this fact was given by Bubeck and Eldan (2015); to complete our story of EW we spell out the proof details.

Concluding Remarks

On average, we all live in an exponentially weighted world.
